

# Understanding Security Concepts in an Enterprise Environment

## Data Masking

-Can be done within applications, databases, etc at the individual record, row, or table.

**Intention:** To hide important data from those who should not access it.

## IP Address masking:

Network Address Translation (NAT) enables private IP addresses to be masked behind a proxy or firewall.

Data masking example:

## Data Masking

```
+-----+-----+
+ name | ssn      |
+-----+-----+
| Alice | 721-07-4426 |
| Bob   | 435-22-3267 |
...
...
```

Unmasked query result

```
+-----+-----+
+ name | ssn      |
+-----+-----+
| Alice | xxxxxxxxxxxx |
| Bob   | xxxxxxxxxxxx |
...
...
```

Masked query result

Masked users **social security numbers** to make them not available to users who should not see it.

## Tokenization:

Replacing sensitive data with non sensitive equivalent.

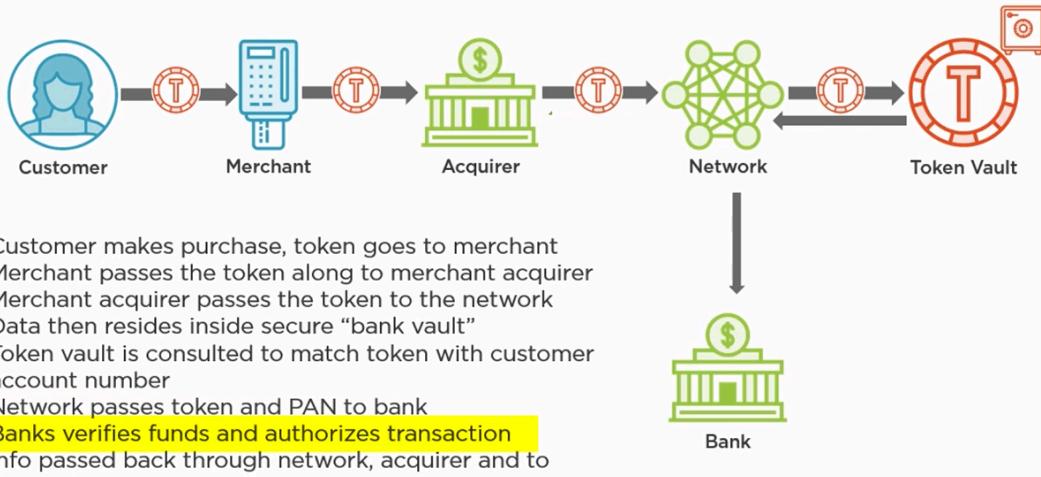

-can be single use, multiple uses, cryptographic, or non cryptographic, irr/reversible, etc.

## Examples:

- High-Value tokens (HVTs) can be used to replace things like primary account #s (PAN) on credit card transactions, can be bound to specific devices.
- Low- value tokens (LVTs) similar to HVTS but needs the underlying tokenization system to match it back to the actual PAN (primary account number)

## Visualization of Tokenization:

## Tokenization Example

## Digital Rights Management (DRM)

Suite of tools to limit how/where content can be accessed.

### Goal:

Prevent content from being copied  
Restrict what devices content can be viewed on.

Examples: MP4, MP3, MOV, etc.

## Hardware Based Encryption (TPM and HSM)

### -TPM (Trusted Platform Module):

A hardware chip embedded on the computer's motherboard. Used to store Cryptographic keys used for encryption.

### -HSM (Hardware Security Module):

Are removable or external devices that can be added later. Both are used for encryption using RSA keys.

## Cloud Access Security Broker:

### Security Policy Enforcement points

- Either on prem or in cloud
- Placed b/t the company (consumer) and the cloud provider.
- Ensures policies are enforced when accessing cloud based assets.

Examples of things controlled:

- Authentication/ Single sign-on
- Credential mapping
- Device profiling
- Logging

## Security- as-a-Service (SECaS)

Cloud provider that can offer security services cheaper and more effective than on-prem.

Why Cloud and not on prem:

- Authentication
- Anti-Virus/malware/Spyware
- Intrusion Detection
- Pen Testing
- SIEM (Security Incident Event Management)

Difference b/t Security as a service (SECaas)and Cloud Access Security Broker (CASB):

## So What's the Difference?

### SECaS

Cloud providers offer their services, infrastructure, resources, etc., to extend into a company's network

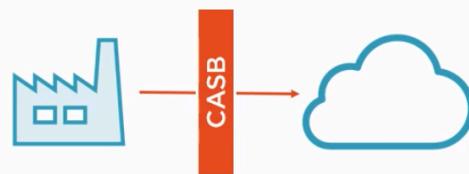

They provide the security services typically at a cheaper TCO than the customer organization can

### CASB

Sits between a customer's network and the cloud, acting as a broker or services gateway

Enforces the customer organization's policies when accessing anything in the cloud

## Recovery

Example: Can users recover their own passwords?

-If so: ensure security Questions are not easily discovered through social engineering.

- Policy defines if a user needs to call a help desk or have self service options.

## Secure protocols:

SSL/TLS

-Secure Sockets Layer/ Transport Layer Security

- Can allow encryption or enable.
  - TLS = newer + based on SSL.
  - Adds confidentiality and data integrity by encapsulating other protocols.
  - TLS version 1.2+ should be used wherever possible.

## Hashing

A mathematical Algorithm applied to a file before or after transmission.

-if anything within the file changes, the hash will be completely different.

Types: MD5, SHA1, SHA2.

- Example (SHA1)
  - Pluralsight really is the best training on the planet!
  - **052ff1f85f58f53d0ad17ef5907ad5fb883d4136**
  - Pluralsight really is the best training on the planet
  - **2f5f50d07cff1a7a15dcfabd793d12d6469ebefbc**

Comparing hashes = good way to verify the integrity of something downloaded.

## API (Application programming interfaces) Considerations:

API Gateways can perform load balancing, virus scanning, orchestration, Authentication, data conversion and more.

Users do not directly interact with API.  
API is handled behind the scenes. What  
changes = interaction with API.

Examples:

- Advanced Security
- Mediation
- Custom API
- Load Balancing
- Caching
- Request Shaping
- Transport Security

Recovery Site Options

## Recovery Site Options

Type of Site	Pros	Cons
Cold Site	<ul style="list-style-type: none"><li>Inexpensive</li></ul>	<ul style="list-style-type: none"><li>Long recovery time (weeks)</li><li>All data lost since last backup</li><li>Funds available to quickly purchase new equipment and/or services</li></ul>
Warm Site	<ul style="list-style-type: none"><li>Relatively inexpensive, cheaper than hot site</li></ul>	<ul style="list-style-type: none"><li>Some equipment (phone, network) but not ready for immediate switch over</li><li>Recovery time could be days to a week or more</li></ul>
Hot Site	<ul style="list-style-type: none"><li>Expensive to very expensive (depending on infrastructure, replication, etc.)</li></ul>	<ul style="list-style-type: none"><li>Duplicate infrastructure must be acquired and maintained</li><li>Bandwidth and location constraints may be in place (synchronous failover/replication)</li></ul>
Cloud Based	<ul style="list-style-type: none"><li>DR-as-a-Service (DRaaS) or Cloud DR</li><li>Managed by provider</li><li>Unlimited backup capacity (perceived)</li></ul>	<ul style="list-style-type: none"><li>Recovery times may be slower</li><li>Confusion around types/best practices (on-prem, off-prem, hybrid, multi-cloud, etc.)</li></ul>

It = important to have data centers that are dispersed in case of disaster.

## Honeypots

- Computers or hosts that are set up TO become targets of attacks.
  - Appear to have sensitive info
  - Monitored to identify hackers or learn their methods and techniques.
- HoneyFiles
  - Similar but applies to individual files designed to entice bad actors and monitor their activities.

## Honeynets

- Similar to Honeypots but larger in scale
- Network setup intentionally for attack so the attackers can be monitored/studied.
- Honeywall = Firewall Honeypot

## Fake Telemetry:

- Applications can pretend to be useful utilities

Examples: Antivirus and antimalware fakes

Claims to find fake viruses/malware, shows report data, etc.

Tricks users into paying for premium support, virus removal.

Can install additional malware

## DNS Sinkhole

- DNS server that supplies false results.

- Can be used constructively or maliciously
- Good use example: DNS sinkhole high up the DNS hierarchy to stop a botnet from operating across the internet
- Bad use: Malicious actors redirecting users to a malicious website.

# Understanding Virtualization and Cloud Computing

**Cloud** = Storage that = external to a company's data.

- Accessible from outside network
- Can be simply storage or automation.

Cloud Storage:

- Access controls
  - Policy around who can access what data
  - Audit third party providers to ensure their security practices are at least as stringent.

- Is data copied to data centers and where are they located?

Cloud Computing:

Virtualization of infrastructure, platform and services.

- Reduced time to market
- Automation and self service
- Increased speed to develop and deliver

Types of Cloud Computing:

Infrastructure as a service (IaaS; “I-as”)

Platform as a Service (PaaS; “pass”)

# Software as a Service (SaaS; “Sass like sassy”)

HA= High availability

DR= Disaster Recovery

# Infrastructure as a Service (IaaS)

## Infrastructure as a Service

IaaS allows for distribution and consumption of resources **as a service**

- Multiple users can utilize the same infrastructure (multi-tenant)
- Allows for elastic scaling as needs and demands increase/decrease

---

-Pay for only what you need and not more or less. It prices things from a utility model and shift from Capex to Opex

-IaaS and Automation is leveraged and is self service, enabling a customer to select their hardware and software configurations.

## Platform as a Service (PaaS)

A PaaS environment = computational resources that can be created and configured.

Is multi tenanted.

Examples of Paas Providers:

- AWS Elastic Beanstalk
- Windows Azure
- Heroku
- Force.com
- Google App Engine
- Apache Stratos
- Openstack (redhat)
- Cloud Foundry (Pivotal)

# Software as a Service

## SaaS

- App that are provided on demand
- No Setup, installation, configuration required.

Examples: Salesforce, Office 365, Google Apps

## IaaS, PaaS and SaaS Differentiators

Infrastructure-as-a-Service  
• You manage the OS up

Platform-as-a-Service  
• You manage the DATA up

Software-as-a-Service  
• You manage nothing

If you're running a Private Cloud, then you are the "vendor" and the customers are the managers

### Infrastructure (As-a-Service)

- Applications
- Data
- Runtime
- Middleware
- O/S
- Virtualization
- Servers
- Storage
- Networking

### Platform (As-a-Service)

- Applications
- Data
- Runtime
- Middleware
- O/S
- Virtualization
- Servers
- Storage
- Networking

### Software (As-a-Service)

- Applications
- Data
- Runtime
- Middleware
- O/S
- Virtualization
- Servers
- Storage
- Networking

 You Manage

 Managed by Vendor

# Managed Service Provider (MSP)

MSP's deliver Services that are either on prem at site of customer, in the MSP's data center or in a third party data center.

- Network
- Application
- Infrastructure
- Security
- An outsource IT and provide 24/7 monitoring.

## On-prem vs. Off-prem

On-prem	Off-prem
You own the infrastructure	Don't own the equipment
More control on customization and non-standard builds	Managed by provider
More direct control over policies, management, administration	Less control over customization, policies and overall administration
Continual upgrade/refresh of infrastructure	No lifecycle or maintenance activities
Capital expenditure (CAPEX) typically	Patching and security managed by provider
	Operating expense (OPEX) typically

## Fog computing

Fog computing extends cloud computing to the network edge.

- Edge computing (processing data local to where it was created) = a subset
- Compromised of compute, Network, and storage

## Edge Computing

- Edge + fog = sometimes interchanged
- Is a subset of fog (storage, compute, and network close to the edge)

# Virtualization

Taking the capabilities and “**personality**” of a physical device and converting to a virtual representation

- Can perform the **same functions** as its physical counterpart
- Lower infrastructure costs
- Increased licensing costs  
(hypervisor license)

Only buy what is needed but increases  
licencing cost

# Types of virtualized servers:

Type 1:

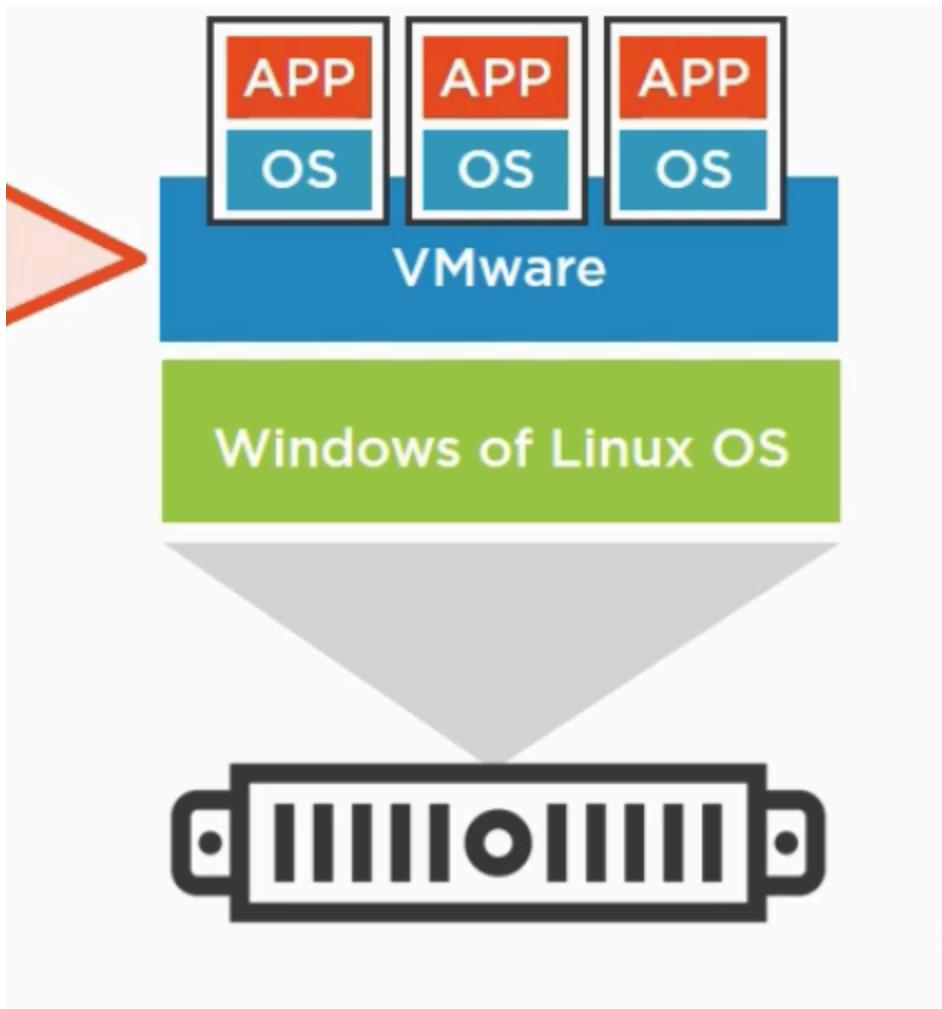

Hosts run on bare metal servers and guests run on the host.

Example: Linux, etc,

Type 2:

Hosts run on top of the OS and guests run inside the host. (i.e. Vmware workstation or Virtual Box)

Runs at third layer above the hardware

Container Based:

Operating System Virtualization:

- lightweight
- containers can start in milliseconds
- Shares OS kernel
- Contains App and binaries

# Microservices Key Points:

## Applications are broken apart by function

All services are created individually and deployed separately from one another

## Each component is loosely coupled

Different groups can develop different functions, and each service can be changed/upgraded without affecting the others

## Deployed via containers

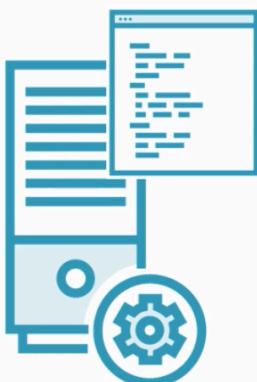

Kubernetes and Docker are typically used and each microservice is packed as a container image

## Quickly scales

Scaling is done based on the changing number of container instances

## Infrastructure as Code (IAC)

### Methodology to create repeatable processes for deploying infrastructure

- Replaces static scripts
- Collaboration and automation tools like Puppet and Chef enable speed of delivery
- Reduces shadow IT, makes processes more secure and reduces risk of human error

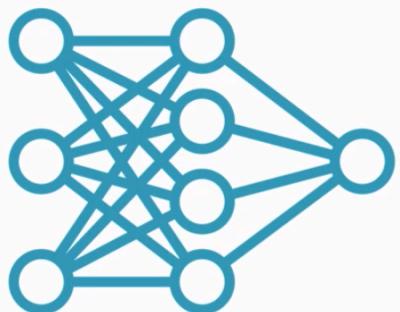

### Software-Defined Networking (SDN)

- Decouples the management plane from the data plane
- Places intelligence higher up the stack
- Wholistic view of the network and programmatic tuning based on activity, workloads, etc.
- Routers/switches become “dumb devices” with intelligence handled by centralized controller suite

## Software Defined Visibility (SDV)

### Software-Defined Visibility (SDV)

#### Software Defined Visibility

- “Visibility fabric” that can be in-line or out of band and monitor entire network
- Proactively respond to events and adjust traffic, shut down ports, log/alert, capture traffic, decrypt/inspect SSL, etc.

## **Serverless architecture**

- Underlying infrastructure is abstracted from user (IaaS, PaaS)
- Only the code is managed/deployed and can scale at the individual call level
- Only pay for the times the function is called vs. paying for an application to be always on and waiting for requests

## **Serverless providers:**

- AWS Lambda, Microsoft Azure Functions and Twilio Functions
